2. Osseointegration

An experimental study¹ comparing uncoated, hydroxyapatite-coated and titanium-coated Orthofix screws was conducted. Osseointegration with direct contact between the bone and the screw thread was seen only with the hydroxyapatite-coated Orthofix screws.

Stainless steel surface: metal screwed into the bone, but no actual bond between them. In a proportion of cases this physical fit breaks down sufficiently to cause macroscopic loosening.

Hydroxyapatite surface: bone grows into and onto the hydroxyapatite so that the border between the two materials becomes indistinct.

This biological bond is a strong anchor which will ensure long-term stability of the bone-screw construct, allowing it to withstand repetitive loading cycles without loosening of the screw.

External fixation is a race between the growing stability provided by callus maturation and the destabilising effect of screw loosening. Preservation of the bone screw interface is the key to a successful outcome.

2. Enhanced Fixation and Reduced Pin Loosening

A clinical study² compared insertion and extraction torques of uncoated and hydroxyapatite-coated Orthofix screws.

Insertion and extraction torques of 38 uncoated and 38 hydroxyapatite-coated Orthofix screws

Mean treatment time: 101 days

- No significant difference in insertion torque between hydroxyapatite-coated and uncoated screws at either site (p= 0.282 metaphyseal site; p= 0.268 diaphyseal site).
- The extraction torque was significantly greater at each site with hydroxyapatite-coated screws than with uncoated screws (p<0.0001 in both anatomical sites)
- The extraction torque of the hydroxyapatite-coated screws was significantly higher than the insertion torque at each site (p<0.0001 metaphyseal site; p= 0.020 diaphyseal site), whereas that of the uncoated screws was significantly lower in both anatomical sites (p<0.0001).
- It was possible to remove the hydroxyapatite-coated screws without the need for hospitalization, sedation or anesthesia.

The same clinical study² demonstrated a significant reduction in the amount of loosening when hydroxyapatite-coated Orthofix screws were used in metaphyseal bone.

Percentage of loose* metaphyseal screws

3. Reduced Incidence of Pin Track Infection

Mean treatment times: Uncoated screws 166 days; HA-coated screws 178 days

- A further clinical study³ demonstrated a significantly lower incidence of pin track infection with hydroxyapatite-coated screws than with uncoated screws (p<0.05).
- A significant correlation between pin track infection and implantation in a metaphyseal site was found with the uncoated screws (p<0.001), but not with the hydroxyapatite-coated screws (p>0.12).

OsteoTite Bone Screws

- Orthofix OsteoTite Bone Screws with Hydroxyapatite Coating may eliminate the need to replace the external fixation system with an alternative treatment for long term therapy.
- Conical thread design:

The hydroxyapatite coating is complemented by the well-established conical design of the Orthofix screws. Each thread cuts a new, slightly larger path in the bone on insertion, providing excellent bone purchase
